(Dated: January 27, 2013)

Using the Ginzburg-Landau theory extended to the next-to-leading order we determine numerically the healing lengths of the two order parameters at the two-gap superconductor/normal metal interface. We demonstrate on several examples that those can be significantly different even in the strict domain of applicability of the Ginzburg-Landau theory. This justifies the use of this theory to describe relevant physics of two-gap superconductors, distinguishing them from their single-gap counterparts. The calculational degree of complexity increases only slightly with respect to the conventional Ginzburg-Landau expansion, thus the extended Ginzburg-Landau model remains numerically far less demanding compared to the full microscopic approaches.

PACS numbers: 74.20.De, 74.70.Ad, 74.70.Xa

Over the past half-century, the Ginzburg-Landau (GL) theory[1] has proven to be a very helpful tool in studies of superconductors, but also other systems in and out of the condensed matter physics. By its construction, the formalism is only justified near the critical temperature T_c, but it typically produces qualitatively correct results even far below the T_c. Recently an exception was found to this unwritten rule, when it was shown that the standard formulation of the GL theory is insufficient for adequate description of two-band (or multi-band) superconductors because it predicts the same spatial variation of the condensates in all bands[2](within its range of applicability i.e. close to T_c). This renders it unable to connect to the theoretical results obtained by using Usadel[3,4] or Eilenberger[5] equations in the broader temperature range, which unambiguously show presence of two separate length scales for two gaps. Experimentally, the evidence for different coherence lengths in σ and π bands of MgB_2 was previously found by the direct vortex imaging[6] and in pronounced features in the behaviour of the thermal conductivity[7], specific heat[8] and flux-flow resistivity[9] as a function of applied magnetic field.

In order to capture the important physics of different length scales, one needs to extend the GL formalism as realized in Ref. 10, where the two order parameters are calculated up to order $\tau^{3/2}$ in the small deviation from the critical temperature $\tau = 1 - T/T_c$, instead of the standard $\tau^{1/2}$ as used in Ref. 2. In the latter article, the authors mention that the extra terms in the next-to-leading order are by construction small corrections, not significant enough to alter the *single* coherence length controlling the spatial distribution of *both* condensates. First, we argue that the effects of higher-order corrections can be significant since the above argument about small corrections applies only to the order parameter - not necessarily to its spatial profile i.e. healing lengths and other physical quantities. Second, we argue that any (even small) difference between the characteristic length scales of two condensates is of fundamental importance, since it may lead to other novel phenomena related to the competition of length scales. Note that here we do not enter the recent debate about sufficient discrepancy of length scales to provide 'type-1.5' superconductivity[11]. Instead, we complement that discussion, by exactly quantifying the difference in length scales in the domain of the extended GL theory.

The fact that the difference of characteristic length scales of two Cooper pair condensates exists and can be significant even in the strict Ginzburg-Landau domain is of great practical importance, since the calculations based on the Ginzburg-Landau theory are typically far less computationally demanding than the calculations based on full microscopic theories (Bogoliubov-de Gennes, Gor'kov, Usadel or Eilenberger equations). In microscopic formalisms, one usually has to make clever approximations and make compromises in the calculation procedure. As a consequence, even though these approaches are valid in the whole temperature range from absolute zero to T_c, they are limited to the simple systems such as a single vortex or other highly symmetric or effectively one-dimensional cases. On the contrary, the Ginzburg-Landau equations have a much simpler structure and therefore allow for studying of highly non-trivial situations such as vortex lattice statics and dynamics, current driven systems, interaction with pinning and fluxonic devices. Since the above is well established in the standard GL formalism, we emphasize here that the calculations become only a fraction more complicated in the extended Ginzburg-Landau formalism - while it does contain more equations (for the order parameters to the leading, and next-to-leading order), the coupling of those equations is realized through the coefficients and not the calculated variables - contrary to the standard set of two-band GL equations[12].

Theoretical formalism Following Ref. 10, we employ the extended GL formalism for the order parameters Δ_j evaluated up to order $\tau^{3/2}$ by taking $\Delta_j(\mathbf{x}) = \Delta_j^{(0)}(\mathbf{x}) + \Delta_j^{(1)}(\mathbf{x})$, where $\Delta_j^{(0)}(\mathbf{x}) \propto \tau^{1/2}$ and $\Delta_j^{(1)}(\mathbf{x}) \propto \tau^{3/2}$, with $j = 1, 2$ indexing two coupled condensates in a two-band superconductor. In the absence of applied magnetic field, the order parameters can be taken real. The extended GL equations then read (at zero magnetic field)

$$\alpha\Delta_j^{(0)} + \beta_j[\Delta_j^{(0)}]^3 - K\nabla^2\Delta_j^{(0)} = 0, \tag{1a}$$

$$\Delta_j^{(1)}\left(\alpha + 3\beta_j[\Delta_j^{(0)}]^2\right) - K\nabla^2\Delta_j^{(1)} = F(\Delta_j^{(0)}) + F_j(\Delta_j^{(0)}), \tag{1b}$$

where $\alpha = -N(0)\tau\left(n_1\mathcal{A}_2 + n_2\mathcal{A}_1\right)/\lambda_{12}$, $K = N(0)\hbar^2 W_3^2\left(n_1 v_1^2\mathcal{A}_2 + n_2 v_2^2\mathcal{A}_1\right)/(6\lambda_{12})$, $\beta_{1(2)} = N(0)W_3^2\Big(n_{1(2)}\mathcal{A}_{2(1)}/\lambda_{12} + n_{2(1)}\mathcal{A}_{1(2)}^3/\lambda_{12}^3\Big)$, with $\mathcal{A}_1 = \lambda_{22} - \eta n_1\mathcal{A}$ and $\mathcal{A}_2 = \lambda_{11} - \eta n_2\mathcal{A}$. Here $\mathcal{A} = \ln(2e^{\Gamma}\hbar\omega_D/\pi T_c)$, with Euler constant $\Gamma = 0.577$, and η denotes the determinant of the interaction matrix $\lambda_{ij} = N(0)g_{ij}$, with g_{ij} the coupling constant, $N(0)$ the total density of states (DOS) and $n_j N(0)$ the band-dependent DOS. In addition, the coefficients feature Fermi velocities v_j of both bands, $W_3^2 = \frac{7\zeta(3)}{8\pi^2 T_c^2}$, with $\zeta(\dots)$ the Riemann zeta-function, and terms F and F_j which are given in complete form in Ref. 10. Since Eq. (1a) is completely equivalent to the single-gap GL equation and the bands share the same critical temperature T_c, we have either *both* bands normal or *both* bands superconducting. In the first case, Eq. (1b) allows only $\Delta_j^{(1)} = 0$ as a solution and thus superconductivity cannot be restored by corrections in the extended GL model. In the following we will consider that both bands are superconducting and their bulk amplitudes $W_j = \sqrt{-\alpha/\beta_j}$ are real. We rescale the equations using $\Delta_j^{(k)} = W_j\tilde{\Delta}_j^{(k)}$ and $x = \xi\tilde{x}$, where $\xi = \sqrt{-K/\alpha}$ is the length unit common for both condensates, and obtain (tildes omitted)

$$\Delta_j^{(0)} - [\Delta_j^{(0)}]^3 + \nabla^2\Delta_j^{(0)} = 0, \tag{2a}$$

$$\Delta_j^{(1)}(1-3[\Delta_j^{(0)}]^2) + \nabla^2\Delta_j^{(1)} = \frac{F(\Delta_j^{(0)}) + F_j(\Delta_j^{(0)})}{\alpha W_j}. \tag{2b}$$

The first equation is the same for both bands, while the second one differs through the terms on the right side. This is exactly the cause for the emergence of two different characteristic lengths in the two bands. From Eq. (2) it is also directly apparent why this does not happen in the order parameters of order $\tau^{1/2}$, i.e. in Eq. (2a), but only in the higher order considerations as in Eq. (2b). To evaluate the coefficients entering Eq. (2) one needs in principle to specify the coupling constants λ_{11}, λ_{22} and λ_{12}, the partial density of states in one band, e.g. n_1 (since $n_1 + n_2 = 1$ this determines n_2 as well), and the ratio of the Fermi velocities v_1/v_2. All other parameters enter units of scaling, and therefore have no impact on any physical effects.

The Ginzburg-Landau domain Before discussing the numerical results of Eqs. (2), it is very important to get a feeling about the relevant values of τ, i.e. *the domain of applicability* of the extended GL model. First of all, our analysis shows that $\tau\Delta_j^{(0)} \sim \Delta_j^{(1)}$. Then, by construction, $\Delta_j^{(0)} > \Delta_j^{(1)}$ and the trivial inequality $\tau < 1$ holds. However, this is a necessary but not sufficient condition justifying Eqs. (2), as one also needs to keep in mind the justification for the use of the gradient expansion in the derivation of Eqs. (2). This expansion requires the GL coherence length ξ to be larger than the band-dependent correlation length $\zeta_j = \hbar v_j/(2\pi T)$ that controls the spatial variations of the relevant kernels in the integral expansion of the anomalous (Gor'kov) Green function in powers of the band-dependent order parameters (in the clean limit), i.e.,

$$\zeta_1, \zeta_2 < \xi. \tag{3}$$

It is important to note here that for a two-band superconductor ζ_j is not necessarily close to the band-dependent generalization of the Pippard length, i.e., $\hbar v_j/(\pi\Delta_j)|_{T=0}$, often used as an estimate of the coherence lengths of two bands[2,13]. Using definitions of α, K and β_j, we obtain from Eq. (3) the following estimate for the GL domain $\tau \lesssim \tau^*$ with

$$\frac{\tau^*}{(1-\tau^*)^2} = 1 + \frac{v_1^2/v_2^2 - 1}{1 + n_2\mathcal{A}_1/(n_1\mathcal{A}_2)} \quad (v_1 < v_2). \tag{4}$$

If $v_1 \geq v_2$, the replacement $1 \leftrightarrow 2$ should be made. The Eq. (4) shows that the extent of the Ginzburg-Landau domain for specific multi-gap superconductor depends on its material parameters, as was first pointed out in Ref. 4. The Eq. (4) is most sensitive to the ratio of the Fermi velocities v_1/v_2. In particular, when $v_1/v_2 = 1$, the above inequality simply implies $\tau \lesssim 0.38$, i.e., the same as in the one-band case, regardless of the particular values of the other parameters, i.e., n_2/n_1 and $\mathcal{A}_2/\mathcal{A}_1$ (where $\mathcal{A}_2/\mathcal{A}_1 = [\Delta_1^{(0)}/\Delta_2^{(0)}]^2$). For $n_1 \approx n_2$ and $\mathcal{A}_1 \approx \mathcal{A}_2$, we typically obtain $0.27 < \tau^* < 0.38$, thus

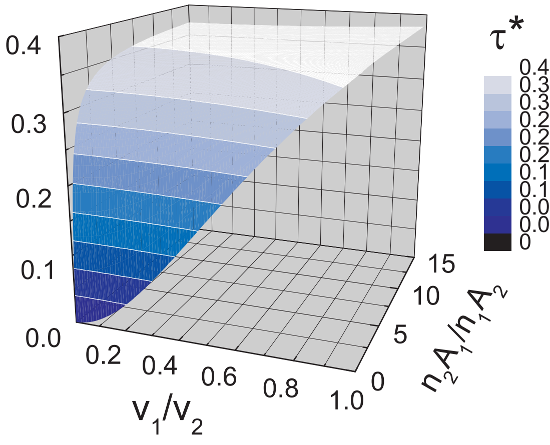

FIG. 1: The estimated temperature range $\tau < \tau^*$ of the validity of the GL theory based on Eq. (4). The gradient expansion made in the derivation of the GL equations (both standard and extended) is fully justified below the plotted 3D-surface.

the temperature domain of GL theory is still very large. The GL domain shrinks significantly only when the ratio $n_2\mathcal{A}_1/(n_1\mathcal{A}_2)$ acquires either extremely large or very small values, which, e.g., can occur when the two energy gaps differ more than an order of magnitude and at the same time v_1 is very different from v_2. For example, for the magnesium diboride parameters (as elaborated further below) one finds from Eq. (4) $\tau^* = 0.08 - 0.32$ depending on the relevant ratio of the Fermi velocities (i.e. on the direction considered, because σ band of magnesium diboride is highly anisotropic), which is an order of magnitude larger than the estimate $\tau^* \approx 0.02$ given in Fig. 1 of Ref. 4. The threshold temperature for the applicability of the GL theory (τ^*) for a broader range of parameters (i.e. other materials) is plotted in Fig. 1.

Different length scales in selected borides, pnictides, and nanothin Pb films To evaluate and compare the spatial distribution of the two order parameters in a two-band superconductor, we study the simple case of a superconductor/normal metal (S/N) interface in the absence of any applied magnetic field. It then suffices to consider the one-dimensional version of Eqs. (2), along the x-axis perpendicular to the S/N interface. The appropriate boundary conditions are $\Delta_j^{(k=0,1)}(x=0) = 0$, and $\nabla\Delta_j^{(k)}(x \to \infty) = 0$, where thus $x = 0$ lies at the interface, with superconductivity fully suppressed there. The second boundary condition ensures unperturbed two-gap superconductivity away from the S/N interface. In Fig. 2(a) we show the results for $\Delta_j(x)$ in MgB$_2$ (normalized to bulk values, at temperature $T = 0.95T_c$, and with other parameters taken from Refs. 13 and 14), obtained within standard[12], extended[10], and reduced[2] GL formalism. In the case of MgB$_2$, the extended GL model clearly gives two length scales for two order parameters $\Delta_{j=1,2}$, *smaller* than those obtained in the standard GL theory (with incomplete higher-order terms).

For correct comparison one must define a measure for the spatial variations of Δ_j. From the numerical solution of Eq. (2a) we found that at the characteristic distance ξ the single-gap-like order parameter $\Delta_j^{(0)}$ increases from zero to 0.6089 of its bulk value Δ_{j0}. Therefore we define the *healing lengths* ξ_j for the two condensates in a two-gap superconductor using the criterion $\Delta_j(\xi_j) \equiv 0.6089\Delta_{j0}$, as depicted in Fig. 2(b). The difference between the characteristic length scales in two bands is clear already from their definition in Fig. 2(b), but we emphasize this point in Figs. 2(c,d), where the ratio of the healing lengths of the two order parameters is plotted as a function of temperature [Fig. 2(c)] and ratio of Fermi velocities v_1/v_2 [Fig. 2(d)]. At the lowest temperature shown in (c), $T = 0.92T_c$, the disparity between the healing lengths is already over 25%, and the difference increases as the ratio of the Fermi velocities is taken smaller [see (d)].

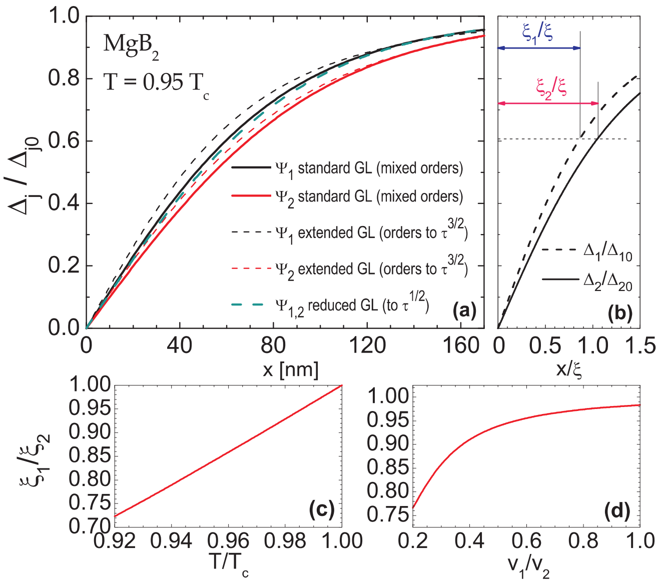

FIG. 2: (a) The spatial profile of the order parameters at the S/N interface at $T = 0.95T_c$, for microscopic parameters of MgB$_2$ ($\xi_1/\xi_2 = v_1/v_2 = 0.255$[13]; $\lambda_{11} = 1.88, \lambda_{22} = 0.5, \lambda_{12} = 0.21$, $n_1 = 0.43$[14]), compared in three versions of the two-band GL theory. The ratio of the healing lengths of the two coupled condensates ξ_1/ξ_2 calculated in extended GL theory [with $\xi_{1,2}$ determined as illustrated in (b)] is shown in (c) as a function of temperature for fixed $v_1/v_2 = 0.255$, and in (d) as a function of the ratio v_1/v_2 at $T = 0.95T_c$.

In the analysis of the above phenomenon we noticed that only the coefficient S in front of the term $\nabla^2\Delta_j^{(0)}$ in $F(\Delta_j^{(0)})$ depends both on τ and v_1/v_2:

$$S = \frac{\hbar^2 N(0) W_3^2 \tau}{6\lambda_{12}} \sum_{j=1,2} v_j^2 (2n_j\lambda_{jj} - \eta n_1 n_2 (1 + 2\mathcal{A})). \quad (5)$$

Due to this special form, for particular values of n_j and λ_{ij} the term in brackets can be positive for one band, but negative for the other. In such a case it is possible to change the sign of S term by varying the ratio of the Fermi velocities v_1/v_2 around its threshold value

$$\left(\frac{v_1}{v_2}\right)^* = \left(-\frac{2n_2\lambda_{22} - \eta n_1 n_2 (1 + 2\mathcal{A})}{2n_1\lambda_{11} - \eta n_1 n_2 (1 + 2\mathcal{A})}\right)^{1/2}, \quad (6)$$

which equals 0.46 for the parameters of Fig. 2. Therefore, two cases with v_1/v_2 significantly larger and smaller than 0.46 will show very different behavior with respect to the disparity of the healing lengths of the two condensates, as is visible in Fig. 2(d). For $v_1/v_2 \approx 0.46$, the term with coefficient S has no influence and other terms determine the spatial behavior of the order parameters.

Besides the difference in the healing lengths of the two condensates, the extended GL model provides insight also in a more accurate temperature dependence of the order parameters. Namely, standard GL theory leaves one with simply $\Delta \propto \tau^{1/2}$, which is shown in Fig. 3 to be clearly inadequate for our calculations. Specifically, in Fig. 3 we show two healing lengths as

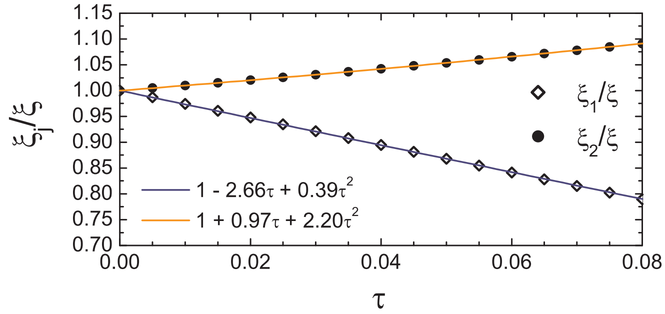

FIG. 3: The healing lengths of the two order parameters in MgB_2 [Fig. 2(a)] scaled to the standard GL length scale ξ as a function of temperature. The lines show the fitting functions of the data.

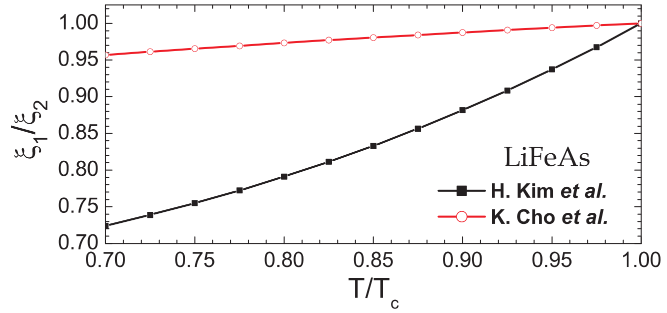

FIG. 4: The temperature dependence of the ratio of the healing lengths ξ_1/ξ_2 in LiFeAs, for parameters from Ref. 16 and Ref. 17.

a function of temperature, both already normalized to the temperature-dependent length $\xi \propto \tau^{-1/2}$. It is directly obvious that we are left with a non-constant value, and we fitted the general temperature-dependence of the residue to a quadratic form $\xi_j/\xi = 1 + A\tau + B\tau^2$, as shown in Fig. 3.[21]

In what follows, we extend our analysis to materials other than MgB_2. We first address the recently discovered iron-pnictides, more specifically LiFeAs. Interestingly enough, several existing experimental works on this material provide us with *radically different* microscopic parameters obtained from the fit of the superfluid density data in the self-consistent γ-model[15,16] and from two-band fitting of the upper critical field[17,18]. In Fig. 4, we show the GL-calculated ratio of the healing lengths of two bands in LiFeAs, for the parameters taken from latter two references. Although different, both curves in Fig. 4 clearly show a discrepancy between the healing lengths, up to 20% at temperatures above $0.8T_c$.

The present study and its conclusions are relevant not only for bulk multi-band materials, but also for nanoscale superconductors, e.g. single-crystalline nanofilms[19], where the multi-band structure appears due to quantum confinement. In particular, the Pb(111) nanofilms with thickness 4 and 5 monolayers are two-band superconductors due to the presence of only two perpendicular single-electron levels below the Fermi energy. Our preliminary analysis of such systems shows that the difference of two healing lengths therein is below 5% in the GL domain. However, in quantum confined systems, either nanofilms or pancake fermionic condensates, the exact position of the bands with respect to the Fermi level (and therefore the v_1/v_2 ratio) can be *tuned* by confinement[20] and with that the discrepancy between the corresponding healing lengths can be significantly enlarged.

Conclusions To summarize, we demonstrated on examples of several multi-gap superconducting materials that characteristic length scales of coupled condensates in two- or multi-band samples can be significantly different from each other in the domain of the extended Ginzburg-Landau theory. This makes our model an excellent tool for further studies of two-band systems, where one expects a plethora of novel physical effects emerging from the competition of different length scales.
